

# Assignment 5

## Assignment 5

### Part 1

- (a)
- (b)
- (c)
- (d)

### Part 1

(a5.pdf)

(a)

why the embedding size used for character-level embeddings is typically lower than that used for word embeddings.

We have to connect all the characters to a word. so if the size of  $e_{char}$  is big, the word vector will be huge and very expensive to compute.

(b)

Write down the total number of parameters in the character-based/word-based embedding model

character-based

$$num = e_{char} \times V_{char} + e_{word} \times e_{char} \times k + e_{word}$$

word\_based

$$num = e_{word} \times V_{word}$$

(c)

*Explain one advantage of using a convolutional architecture rather than a recurrent architecture for this purpose.*

It is much easier for CNN to compute in parallel, so it is much faster. Besides, CNN focuses more on part of the word, and RNN focus the whole word.

**(d)**

*In lectures we learned about both max-pooling and average-pooling. For each pooling method, please explain one advantage in comparison to the other pooling method.*

max-pooling can discard something not so important and focus on the most important part.

average-pooling can know the whole information. (But sometimes it is bad to know all the stuff cause you cannot judge what you need to take out) (Less is more)
